Abstract

We study the generalized Dirac-Born-Infeld (DBI) action, which describes a q -brane ending on a p -brane with a $(q+1)$ -form background. This action has the equivalent descriptions in commutative and non-commutative settings, which can be shown from the generalized metric and Nambu-Sigma model. We mainly discuss the dimensional reduction of the generalized DBI at the massless level on the flat spacetime and constant antisymmetric background in the case of flat spacetime, constant antisymmetric background and the gauge potential vanishes for all time-like components. In the case of $q = 2$, we can do the dimensional reduction to get the DBI theory. We also try to extend this theory by including a one-form gauge potential.

1 Introduction

In string theory, the T-duality shows the equivalence of two theories that look different under the exchange of a radii R and α'/R . For the closed strings [1, 2], the T-duality of closed strings exchanges winding and momentum modes. In the case of open strings, the T-duality of open strings exchanges the Dirichlet and Neumann boundary conditions. The studies of the T-duality pave the way for the unified theory. One way is to study the low energy effective action. It is well-known that the DBI model can be derived from the one-loop β function. The low-energy effective field theory (higher derivative gravity [3] or non-local theory) can be directly found from the one-loop β function. Nevertheless, we encounter the non-geometry or T-fold problem in the massless closed string theory. This problem is generic and unavoidable in string theory. To solve this problem, we need to construct geometric languages to endow string theory with a global geometry. Double field theory [4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19] and generalized geometry [20, 21, 22] are two typical examples. This new “stringy geometry” [23, 24] geometrize the non-geometric flux and find the 10-dimensional supergravity with the non-geometric flux as shown in [25, 26]. At the current stage, the most non-trivial problem is that the double field theory needs the section conditions to have gauge invariance. The approaches of relaxing the section conditions can be found in [27, 28, 29]. The extension of the α' correction explores a geometric way to find the T-duality with α' correction [30, 31]. The geometric structure can also be extended to the 11-dimensional supergravity [32, 33, 34, 35, 36, 37]. Some recent good reviews can be found in [38, 39, 40].

To get a geometric picture of brane theory, a combination of non-commutative gauge theory and the generalized geometry is necessary. The non-commutative gauge theory of the D-brane is already well-known, but the non-commutative gauge theory of the M-brane is still not completely understood [41, 42]. Recently, theories based on the equivalence between the commutative and non-commutative gauge theories are found. The theories are the Nambu-Sigma model and generalized DBI model [43, 44]. The non-commutative geometry is encoded in the generalized metric, which is an ingredient of the generalized geometry. Although they do not use the full language of the generalized geometry [45, 46], they found the evidence for the DBI-like M2-M5 system [47].

The main task of this paper is to calculate the dimensional reduction of the generalized DBI theory at the massless level. We perform the dimensional reduction from a $(q + 1)$ -

brane ending on a $(p + 1)$ -brane to a q -brane ending on a p -brane. We consider flat spacetime, constant antisymmetric background field and the $(q + 1)$ -form gauge field only exists in $(q + 1)$ -dimensional worldvolume directions (no time direction) in q - p system. The non-trivial result of this theory is that the appearance of the $2(q + 1)$ -th root, which can be shown by the equivalence between the commutative and non-commutative descriptions, is robust against the dimensional reduction. The most interesting study is the system of a 2-brane ending on a 5-brane. The system can be reduced to a 1-brane ending on a 4-brane by the dimensional reduction. This shows that the system of a 2-brane ending on a 5-brane can be reduced to the DBI theory in our simple consideration. Finally, we discuss the possibility of adding one-form gauge field in the generalized DBI theory. We can include one-form gauge field up to H^2 in principle, and the calculation also demonstrates the potential to extend the generalized DBI theory with different field contents. This study should give the simplest understood of the higher-form fields although it is not a general consideration. Our study on the generalized DBI theory should motivate interest of duality structure in higher dimensions.

The plan of this paper is to first review the generalized DBI theory in Sec. 2. Then we discuss the dimensional reduction without scalar fields in Sec. 3 and dimensional reduction with scalar fields in Sec. 4. Finally, we conclude in Sec. 5. We also provide the detailed calculation in A and B.

2 Review of the Generalized DBI

In this section, we follow [43, 44] to review the generalized DBI theory. First of all, we show the closed-open string relations from the string sigma model. Secondly, we generalize the Poisson-Sigma model to Nambu-Sigma model. We obtain the generalized closed-open relations from the Nambu-Sigma model. Then we introduce the membrane action, which is equivalent to the Nambu-Sigma model under the gauge fixing. In the end of this section, we use the generalized closed-open relations to construct an action.

We define our notations as follow. We denote the worldvolume directions from A to H and indicate the transverse directions from I to Z . The index $a=1, 2, \dots, p$ are reserved for the spatial components of worldvolume coordinates (We denote them from a to h .), while the Greek letters $\mu, \nu, \rho, \sigma=0, 1, \dots, D - 1$ denote the target space indices and $w=0, 1$ denote the world-sheet index. In addition, we use i, j to label the antisymmetric

indices, $i = (i_1, i_2, \dots, i_r)$ with $0 \leq i_1 < i_2 < \dots < i_r \leq (r+1)$, where r is the dimension of i .

2.1 Closed-Open Relations

We first introduce the action of the Poisson-Sigma model

$$S_P = \int_{\Sigma} \left(A_{\mu} \wedge dX^{\mu} - \frac{1}{2} \Pi^{\mu\nu} A_{\mu} \wedge A_{\nu} \right), \quad \Pi \equiv \frac{1}{2} \Pi^{\mu\nu}(X) \partial_{\mu} \wedge \partial_{\nu}, \quad (1)$$

where $X : \Sigma \rightarrow M$, Σ is the two dimensional world-sheet and M is the target space manifold. The one-form field $A(\sigma)$ is on Σ and Π is an antisymmetric tensor. From the equations of motion

$$dX^{\mu} - \Pi^{\mu\nu} A_{\nu} = 0, \quad dA_{\mu} + \frac{1}{2} \partial_{\mu} \Pi^{\nu\rho} A_{\nu} \wedge A_{\rho} = 0, \quad (2)$$

we show that the bi-vector Π satisfies the Jacobi identity. These are the equations of motion for A_{μ} and X^{μ} , respectively. We can add a metric term in the Poisson-Sigma model to obtain the non-topological generalized Poisson-Sigma model

$$S_P = \int_{\Sigma} \left(A_{\mu} \wedge dX^{\mu} - \frac{1}{2} \Pi^{\mu\nu} A_{\mu} \wedge A_{\nu} - \frac{1}{2} (G^{-1})^{\mu\nu} A_{\mu} \wedge *A_{\nu} \right), \quad (3)$$

where $*A_{\nu}$ is the Hodge dual of A_{ν} . The signature of the world-sheet is $(-, +)$ and volume form $d^2\sigma \equiv d\sigma^0 \wedge d\sigma^1$. The $A_{\mu} \equiv A_{\mu w}(\sigma) d\sigma^w$ is an auxiliary field. By using the equation of motion of A_{μ} , the action (3) can be rewritten as the string sigma model action,

$$S_S = - \int_{\Sigma} \frac{1}{2} (g_{\mu\nu} dX^{\mu} \wedge *dX^{\nu} + B_{\mu\nu} dX^{\mu} \wedge dX^{\nu}), \quad (4)$$

where the g and B are defined by the closed-open string relations

$$\frac{1}{g+B} = G^{-1} + \Pi, \Rightarrow \quad G = g - Bg^{-1}B, \quad \Pi = -G^{-1}Bg^{-1} = -g^{-1}BG^{-1}. \quad (5)$$

The action (3) can also be rewritten in terms of the components of $\eta_{\mu} \equiv -A_{\mu 1}(\sigma)$ and $\tilde{\eta}_{\nu} \equiv A_{\nu 0}(\sigma)$, the action is

$$S_P = \int d^2\sigma \left[-\frac{1}{2} (G^{-1})^{\mu\nu} \eta_{\mu} \eta_{\nu} + \frac{1}{2} (G^{-1})^{\mu\nu} \tilde{\eta}_{\mu} \tilde{\eta}_{\nu} + \eta_{\mu} \partial_0 X^{\mu} + \tilde{\eta}_{\mu} \partial_1 X^{\mu} - \Pi^{\mu\nu} \eta_{\mu} \tilde{\eta}_{\nu} \right]. \quad (6)$$

We can use matrix notation to rewrite the action by using

$$\eta \equiv \eta_\mu, \quad \tilde{\eta} \equiv \tilde{\eta}_\nu, \quad G \equiv G_{\mu\nu}, \quad X \equiv X^\mu, \quad \Pi \equiv \Pi^{\mu\nu}. \quad (7)$$

The action becomes

$$S_P = \int d^2\sigma \left(-\frac{1}{2}\eta^T G^{-1}\eta + \frac{1}{2}\tilde{\eta}^T G^{-1}\tilde{\eta} + \partial_0 X^T \eta + \partial_1 X^T \tilde{\eta} - \eta^T \Pi \tilde{\eta} \right), \quad (8)$$

where the superscript T indicates transpose of matrix. By using the matrix notation, it is easier to generalize the Poisson-Sigma model.

2.2 Generalized Closed-Open Relations

The Nambu-Sigma model is a generalization of the Poisson-Sigma model. The action is given by

$$S_N = \int d^{q+1}\sigma \left(-\frac{1}{2}\eta^T G^{-1}\eta + \frac{1}{2}\tilde{\eta}^T \tilde{G}^{-1}\tilde{\eta} + \partial_0 X^T \eta + \tilde{\partial} X^T \tilde{\eta} - \eta^T \Pi \tilde{\eta} \right), \quad (9)$$

where

$$\tilde{G}_{ij} = \sum_{\pi} \text{sgn}(\pi) G_{i_{\pi(1)}j_1} \cdots G_{i_{\pi(p)}j_p} \quad (10)$$

with a permutation π . The antisymmetric product of partial derivatives is defined as

$$\tilde{\partial} X^i \equiv \sum_{a_1, \dots, a_q=1}^q \epsilon^{a_1 a_2 \dots a_q} \partial_{a_1} X^{i_1} \cdots \partial_{a_q} X^{i_q}, \quad (11)$$

where $0 \leq i_1 < \cdots < i_q \leq (q+1)$. There are two types of the metrics G and \tilde{G} , auxiliary fields η and $\tilde{\eta}$, and an antisymmetric $(q+1)$ -form tensor Π . We can integrate out the fields η and $\tilde{\eta}$. Then the resulting action is

$$S_b = \frac{1}{2} \int d^{q+1}\sigma \left(\partial_0 X^T g \partial_0 X - \tilde{\partial} X^T \tilde{g} \tilde{\partial} X \right) - \int d^{q+1}\sigma \partial_0 X^T C \tilde{\partial} X, \quad (12)$$

where

$$g \equiv g_{\mu\nu}, \quad \tilde{g} \equiv \tilde{g}_{ij}, \quad C \equiv C_{\mu i}. \quad (13)$$

We identify g , \tilde{g} and C as

$$g = \left(G^{-1} + \Pi \tilde{G} \Pi^T \right)^{-1}, \quad \tilde{g} = \left(\tilde{G}^{-1} + \Pi^T G \Pi \right)^{-1}, \quad C = -g \Pi \tilde{G} = -G \Pi \tilde{g}. \quad (14)$$

In the case of $q = 1$, these relations are reduced to the closed-open string relations (5). We rewrite the action after the Wick rotation ($\sigma^0 \rightarrow -i\sigma^0$) in the compact matrix form

$$S_{bE} = \frac{1}{2} \int d^{q+1}\sigma \, V^\dagger \begin{pmatrix} g & C \\ -C^T & \tilde{g} \end{pmatrix} V, \quad (15)$$

where

$$\exp(iS_b) = \exp(-S_{bE}), \quad V \equiv \begin{pmatrix} i\partial_0 X^\mu \\ \widetilde{\partial X^i} \end{pmatrix}. \quad (16)$$

Let \mathcal{G} denote the matrix

$$\mathcal{G} \equiv \begin{pmatrix} g & C \\ -C^T & \tilde{g} \end{pmatrix}. \quad (17)$$

The inverse matrix is given by

$$\mathcal{G}^{-1} = \begin{pmatrix} (g + C\tilde{g}^{-1}C^T)^{-1} & -(g + C\tilde{g}^{-1}C^T)^{-1}C\tilde{g}^{-1} \\ \tilde{g}^{-1}C^T(g + C\tilde{g}^{-1}C^T)^{-1} & (\tilde{g} + C^Tg^{-1}C)^{-1} \end{pmatrix}, \quad (18)$$

where we used the analytic inversion formula

$$\begin{aligned} \begin{pmatrix} a & b \\ c & d \end{pmatrix}^{-1} &= \begin{pmatrix} a^{-1} + a^{-1}b(d - ca^{-1}b)^{-1}ca^{-1} & -a^{-1}b(d - ca^{-1}b)^{-1} \\ -(d - ca^{-1}b)^{-1}ca^{-1} & (d - ca^{-1}b)^{-1} \end{pmatrix} \\ &= \begin{pmatrix} (a - bd^{-1}c)^{-1} & -(a - bd^{-1}c)^{-1}bd^{-1} \\ -d^{-1}c(a - bd^{-1}c)^{-1} & d^{-1} + d^{-1}c(a - bd^{-1}c)^{-1}bd^{-1} \end{pmatrix}. \end{aligned} \quad (19)$$

We also have

$$\begin{aligned} \mathcal{H} &\equiv \begin{pmatrix} G & \Phi \\ -\Phi^T & \tilde{G} \end{pmatrix}^{-1} + \begin{pmatrix} 0 & \Pi \\ -\Pi^T & 0 \end{pmatrix} \\ &= \begin{pmatrix} (G + \Phi\tilde{G}^{-1}\Phi^T)^{-1} & -(G + \Phi\tilde{G}^{-1}\Phi^T)^{-1}\Phi\tilde{G}^{-1} + \Pi \\ \tilde{G}^{-1}\Phi^T(G + \Phi\tilde{G}^{-1}\Phi^T)^{-1} - \Pi^T & (\tilde{G} + \Phi^TG^{-1}\Phi)^{-1} \end{pmatrix}. \end{aligned} \quad (20)$$

Interestingly, we can get the relations, which is similar to the closed-open string relations by setting $\mathcal{G}^{-1} = \mathcal{H}$. These relations are called generalized closed-open relations. These relations are

$$g + C\tilde{g}^{-1}C^T = G + \Phi\tilde{G}^{-1}\Phi^T, \quad \tilde{g} + C^Tg^{-1}C = \tilde{G} + \Phi^TG^{-1}\Phi, \quad (21)$$

$$g^{-1}C = G^{-1}\Phi - \Pi\left(\tilde{G} + \Phi^T G^{-1}\Phi\right), \quad \Phi\tilde{G}^{-1} = C\tilde{g}^{-1} + \left(g + C\tilde{g}^{-1}C^T\right)\Pi. \quad (22)$$

These relations imply that we can interchange

$$g \leftrightarrow G, \quad \tilde{g} \leftrightarrow \tilde{G}, \quad C \leftrightarrow \Phi, \quad \Pi \leftrightarrow -\Pi \quad (23)$$

to write the action in terms of G , Φ and Π . When $q = 1$, we obtain

$$\frac{1}{g+B} = \frac{1}{G+\Phi} + \Pi. \quad (24)$$

We use $\mathcal{G} = \mathcal{H}^{-1}$ to get another form of the generalized closed-open relations as well.

$$\begin{pmatrix} g & C \\ -C^T & \tilde{g} \end{pmatrix} = \mathcal{H}^{-1}. \quad (25)$$

The results are

$$\begin{aligned} g^{-1} &= \left(1 - \Phi\Pi^T\right)^T G^{-1} \left(1 - \Phi\Pi^T\right) + \Pi\tilde{G}\Pi^T, \\ \tilde{g}^{-1} &= \left(1 - \Phi^T\Pi\right)^T \tilde{G}^{-1} \left(1 - \Phi^T\Pi\right) + \Pi^T G \Pi, \\ C &= \left[\left(1 - \Phi\Pi^T\right)^T G^{-1} \left(1 - \Phi\Pi^T\right) + \Pi\tilde{G}\Pi^T\right]^{-1} \left[\left(1 - \Phi\Pi^T\right)^T G^{-1}\Phi - \Pi\tilde{G}\right]. \end{aligned} \quad (26)$$

Please refer to A for the detailed computations.

We can also use the generalized metric to derive the generalized closed-open relations. The generalized metric is exactly the matrix in the Hamiltonian. Starting from

$$S_{bE} = \frac{1}{2} \int d^{q+1}\sigma \, V^\dagger \begin{pmatrix} g & C \\ -C^T & \tilde{g} \end{pmatrix} V, \quad (27)$$

we get the Hamiltonian

$$\begin{aligned} H[X, P] &= \int d^q\sigma \left(\partial_0 X^T P - S_{bE} \right) \\ &= \int d^q\sigma \left[\partial_0 X^T \left(g \partial_0 X - i C \widetilde{\partial X} \right) - \frac{1}{2} \partial_0 X^T g \partial_0 X - \frac{1}{2} \widetilde{\partial X}^T \tilde{g} \widetilde{\partial X} + i \partial_0 X^T C \widetilde{\partial X} \right] \\ &= \int d^q\sigma \left(\frac{1}{2} \partial_0 X^T g \partial_0 X - \frac{1}{2} \widetilde{\partial X}^T \tilde{g} \widetilde{\partial X} \right) \\ &= -\frac{1}{2} \int d^q\sigma \begin{pmatrix} iP \\ \widetilde{\partial X}^i \end{pmatrix}^T \begin{pmatrix} g^{-1} & -g^{-1}C \\ -C^T g^{-1} & \tilde{g} + C^T g^{-1}C \end{pmatrix} \begin{pmatrix} iP \\ \widetilde{\partial X}^i \end{pmatrix}, \end{aligned} \quad (28)$$

where P is the canonical momentum corresponding to the field X , i.e., $P = g\partial_0 X - iC\widetilde{\partial X}$. If we take $q = 1$, the matrix in Hamiltonian is the usual generalized metric.

We can use another way to write the generalized metric

$$\begin{aligned}
& \begin{pmatrix} 1 & \Pi \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\Phi^T & 1 \end{pmatrix} \begin{pmatrix} G^{-1} & 0 \\ 0 & \tilde{G} \end{pmatrix} \begin{pmatrix} 1 & -\Phi \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \Pi^T & 1 \end{pmatrix} \\
&= \begin{pmatrix} (1 - \Pi\Phi^T)G^{-1}(1 - \Phi\Pi^T) + \Pi\tilde{G}\Pi^T & -(1 - \Pi\Phi^T)G^{-1}\Phi + \Pi\tilde{G} \\ -\Phi^T G^{-1}(1 - \Phi\Pi^T) + \tilde{G}\Pi^T & \Phi^T G^{-1}\Phi + \tilde{G} \end{pmatrix} \\
&= \begin{pmatrix} g^{-1} & -g^{-1}C \\ -C^T g^{-1} & \tilde{g} + C^T g^{-1}C \end{pmatrix}. \tag{29}
\end{aligned}$$

We used (21) and (22) to get the second equality. In other words, we can get the generalized closed-open relations from the generalized metric.

2.3 Membrane Action

Starting from the action

$$S_M = - \int d^{q+1}\sigma \sqrt{-\det(g_{\mu\nu}\partial_A X^\mu \partial_B X^\nu)}, \tag{30}$$

we introduce an auxiliary field h_{AB} and write a classically equivalent action

$$S_{Mc} = -\frac{1}{2} \int d^{q+1}\sigma \sqrt{-\det h} \left(g_{\mu\nu} h^{AB} \partial_A X^\mu \partial_B X^\nu - (q-1) \right). \tag{31}$$

We used an equation of motion of h^{AB}

$$\frac{1}{2} h_{AB} \left(h^{CD} \partial_C X^\mu \partial_D X^\nu g_{\mu\nu} - (q-1) \right) = \partial_A X^\mu \partial_B X^\nu g_{\mu\nu} \tag{32}$$

to derive the equivalence. For $q \neq 1$, we have

$$h^{AB} \partial_A X^\mu \partial_B X^\nu g_{\mu\nu} = q + 1. \tag{33}$$

Therefore, we get $h_{AB} = \partial_A X^\mu \partial_B X^\nu g_{\mu\nu}$. After fixing (by reparametrization invariance) the components h_{a0}, h_{0b} and h_{00} by choosing $h_{a0} = h_{0b} = 0$ and $h_{00} = -\det(h_{ab})$, and using the equation of motion of h^{ab}

$$h_{ab} \left(h^{cd} \partial_c X^\mu \partial_d X^\nu g_{\mu\nu} - (q-1) \right) = \partial_a X^\mu \partial_b X^\nu g_{\mu\nu}, \tag{34}$$

we get the classical equivalence with the gauge fixing

$$S_{\text{gf}} = \frac{1}{2} \int d^{q+1} \sigma \left[g_{\mu\nu} \partial_0 X^\mu \partial_0 X^\nu - \det \left(g_{\mu\nu} \partial_a X^\mu \partial_b X^\nu \right) \right]. \quad (35)$$

The action (35) can be rewritten as

$$S_{\text{gf}} = \frac{1}{2} \int d^{q+1} \sigma \left(\partial_0 X g \partial_0 X - \widetilde{\partial X} \widetilde{g} \widetilde{\partial X} \right). \quad (36)$$

We can add a $(q+1)$ -form background term, $\frac{1}{(q+1)!} C_{i_1 i_2 \dots i_{q+1}} dx^{i_1} dx^{i_2} \dots dx^{i_{q+1}}$. The action is

$$S_C = - \int d^{q+1} \sigma \partial_0 X C \widetilde{\partial X}. \quad (37)$$

We combine S_{gf} with S_C to get the same action as the Nambu-Sigma model.

2.4 Generalized DBI

Before we generalize the DBI action, we first review the well-known theory, DBI theory, which is an effective action for an open string ending on a D-brane. The action is

$$- \frac{1}{g_s} \int d^{p+1} x \sqrt{-\det(g + B + F)} = - \frac{1}{g_s} \int d^{p+1} x \left(-\det g \right)^{\frac{1}{4}} \left[-\det \left(g - (B + F) g^{-1} (B + F) \right) \right]^{\frac{1}{4}},$$

where g_s , g and B are closed string coupling constant, metric and two-form antisymmetric background. F is the abelian field strength ($F \equiv dA$). Before showing the equivalence between the commutative and non-commutative descriptions, we shall discuss the relations between the closed and open string parameters. These are

$$G_s = g_s \left(\frac{\det(G + \Phi)}{\det(g + B)} \right)^{\frac{1}{2}}, \quad (38)$$

$$g - B g^{-1} B = G - \Phi G^{-1} \Phi, \quad B g^{-1} = \Phi G^{-1} - \left(G - \Phi G^{-1} \Phi \right) \Pi. \quad (39)$$

These relations imply that we can determine the open string variables from closed string variables by choosing Π . We can further rewrite G_s as

$$G_s = g_s \left(\frac{\det(G + \Phi)}{\det(g + B)} \right)^{\frac{1}{2}} = g_s \left(\frac{\det G}{\det g} \right)^{\frac{1}{4}} \left(\frac{\det(G - \Phi G^{-1} \Phi)}{\det(g - B g^{-1} B)} \right)^{\frac{1}{4}} = g_s \left(\frac{\det G}{\det g} \right)^{\frac{1}{4}}. \quad (40)$$

Then we include the gauge field in the generalized metric

$$\begin{aligned}
& \begin{pmatrix} 1 & F \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & B \\ 0 & 1 \end{pmatrix} \begin{pmatrix} g & 0 \\ 0 & g^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -B & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -F & 1 \end{pmatrix} \\
&= \begin{pmatrix} g - (B + F)g^{-1}(B + F) & (B + F)g^{-1} \\ -g^{-1}(B + F) & g^{-1} \end{pmatrix} \\
&= \begin{pmatrix} 1 & F \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \Pi & 1 \end{pmatrix} \begin{pmatrix} 1 & \Phi \\ 0 & 1 \end{pmatrix} \begin{pmatrix} G & 0 \\ 0 & G^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\Phi & 1 \end{pmatrix} \begin{pmatrix} 1 & -\Pi \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -F & 1 \end{pmatrix} \\
&= \begin{pmatrix} 1 & F \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \Pi & 1 \end{pmatrix} \begin{pmatrix} 1 & -F' \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & (\Phi + F') \\ 0 & 1 \end{pmatrix} \begin{pmatrix} G & 0 \\ 0 & G^{-1} \end{pmatrix} \\
&\quad \cdot \begin{pmatrix} 1 & 0 \\ -(\Phi + F') & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ F' & 1 \end{pmatrix} \begin{pmatrix} 1 & -\Pi \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -F & 1 \end{pmatrix}. \tag{41}
\end{aligned}$$

We add one new block matrix N to factorize the generalized metric. Later we will combine them to get the equivalence between the non-commutative and commutative descriptions.

$$\begin{pmatrix} 1 & 0 \\ \Pi' & 1 \end{pmatrix} \begin{pmatrix} N^T & 0 \\ 0 & N^{-1} \end{pmatrix} \begin{pmatrix} 1 & \Phi' \\ 0 & 1 \end{pmatrix} \begin{pmatrix} G & 0 \\ 0 & G^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\Phi' & 1 \end{pmatrix} \begin{pmatrix} N & 0 \\ 0 & (N^{-1})^T \end{pmatrix} \begin{pmatrix} 1 & -\Pi' \\ 0 & 1 \end{pmatrix}, \tag{42}$$

where $\Phi' = \Phi + F'$. From

$$\begin{aligned}
& \begin{pmatrix} 1 & 0 \\ \Pi' & 1 \end{pmatrix} \begin{pmatrix} N^T & 0 \\ 0 & N^{-1} \end{pmatrix} = \begin{pmatrix} N^T & 0 \\ \Pi' N^T & N^{-1} \end{pmatrix} \\
&= \begin{pmatrix} 1 & F \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \Pi & 1 \end{pmatrix} \begin{pmatrix} 1 & -F' \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 + F\Pi & -(1 + F\Pi)F' + F \\ \Pi & -\Pi F' + 1 \end{pmatrix}, \tag{43}
\end{aligned}$$

we can obtain

$$\begin{aligned}
\Pi' &= (1 + \Pi F)^{-1} \Pi = \Pi (1 + F \Pi)^{-1}, \\
F' &= F (1 + \Pi F)^{-1} = (1 + F \Pi)^{-1} F, \\
N &= 1 + \Pi F. \tag{44}
\end{aligned}$$

We find useful formulae from

$$\begin{aligned}
& \begin{pmatrix} 1 & 0 \\ \Pi' & 1 \end{pmatrix} \begin{pmatrix} N^T & 0 \\ 0 & N^{-1} \end{pmatrix} \begin{pmatrix} 1 & \Phi' \\ 0 & 1 \end{pmatrix} \begin{pmatrix} G & 0 \\ 0 & G^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\Phi' & 1 \end{pmatrix} \begin{pmatrix} N & 0 \\ 0 & (N^{-1})^T \end{pmatrix} \begin{pmatrix} 1 & -\Pi' \\ 0 & 1 \end{pmatrix} \\
&= \begin{pmatrix} g - (B + F)g^{-1}(B + F) & (B + F)g^{-1} \\ -g^{-1}(B + F) & g^{-1} \end{pmatrix}. \tag{45}
\end{aligned}$$

Hence, we obtain

$$\begin{aligned}
g - (B + F)g^{-1}(B + F) &= N^T \left(G - \Phi' G^{-1} \Phi' \right) N, \\
(B + F)g^{-1} &= -N^T \left(G - \Phi' G^{-1} \Phi' \right) N \Pi' + N^T \Phi' G^{-1} (N^T)^{-1}, \\
g^{-1} &= -\Pi' N^T G N \Pi' + \left(\Pi' N^T \Phi' + N^{-1} \right) G^{-1} \left(\Phi' N \Pi' + (N^T)^{-1} \right).
\end{aligned}$$

Thus, we have

$$\begin{aligned}
\det \left(g - (B + F)g^{-1}(B + F) \right) &= \det^2(N) \det \left(G - \Phi' G^{-1} \Phi' \right), \\
(g + B + F)^{-1} &= \Pi' + \left(N^T (G + \Phi') N \right)^{-1}. \tag{46}
\end{aligned}$$

The DBI action can be rewritten in terms of the closed string parameters instead of the open string parameters by using the above relations:

$$\begin{aligned}
& -\frac{1}{g_s} \left(-\det(g + B + F) \right)^{\frac{1}{2}} \\
&= -\frac{1}{g_s} \left(-\det g \right)^{\frac{1}{4}} \left[-\det \left(g - (B + F)g^{-1}(B + F) \right) \right]^{\frac{1}{4}} \\
&= -\frac{1}{g_s} \left(-\det g \right)^{\frac{1}{4}} \det^{\frac{1}{2}}(1 + \Pi F) \left[-\det \left(G - \Phi' G^{-1} \Phi' \right) \right]^{\frac{1}{4}} \\
&= -\frac{1}{G_s} \det^{\frac{1}{2}}(1 + \Pi F) \left(-\det G \right)^{\frac{1}{4}} \left[-\det \left(G - \Phi' G^{-1} \Phi' \right) \right]^{\frac{1}{4}} \\
&= -\frac{1}{G_s} \det^{\frac{1}{2}}(1 + \Pi F) \left[-\det \left(G + \Phi' \right) \right]^{\frac{1}{2}}. \tag{47}
\end{aligned}$$

Then we perform the Seiberg-Witten map to get

$$- \int d^{p+1}x \frac{1}{g_s} \left(-\det(g + B + F) \right)^{\frac{1}{2}} = - \int d^{p+1}\hat{x} \frac{1}{\hat{G}_s} \det^{\frac{1}{2}} \left(\frac{\hat{\Pi}}{\Pi} \right) \left[-\det \left(\hat{G} + \hat{\Phi}' \right) \right]^{\frac{1}{2}}, \quad (48)$$

where the superscript $\hat{}$ means that the fields are evaluated at the *covariant coordinates*, which comes from the change of coordinates, $x \mapsto \rho_A^*(x) = \hat{x} = x + \Pi \hat{A}$ induced by a map $\Pi \mapsto \Pi' = (1 + \Pi F)^{-1} \Pi$. The coordinate \hat{x}^μ is called *covariant coordinate*. We used

$$\det(1 + \Pi F) = \det \left(\frac{\hat{\Pi}}{\Pi} \right) \det^2 \left(\frac{\partial x}{\partial \hat{x}} \right) \quad (49)$$

to establish the equivalence between the non-commutative and commutative descriptions in the DBI theory.

We expect the generalization of the DBI theory can be done in the similar construction. The generalized DBI action is first proposed in [43]. They use the equivalence between the non-commutative and commutative descriptions to construct the generalized DBI theory. In the generalized DBI theory, the antisymmetric background field is $(q+1)$ -form rather than the 2-form antisymmetric background field in the DBI theory. When $q=1$, the generalized DBI action is naturally reduced to the DBI theory.

We include the details of the calculations in B. Among these, the two following formulae are crucial to determine the generalized DBI,

$$\det \left(g + (C + H) \tilde{g}^{-1} (C + H)^T \right) = \det^2 \left(1 - H \Pi^T \right) \det \left(G + \Phi' \tilde{G}^{-1} \Phi'^T \right). \quad (50)$$

$$\det \left(1 - \Pi^T H \right) = \det \left(1 - H \Pi^T \right) = \det \left(\frac{\hat{\Pi}}{\Pi} \right) \det^{q+1} \left(\frac{\partial x}{\partial \hat{x}} \right). \quad (51)$$

It is obvious that if there is a term like (50), we would get a term $\left(\det \frac{\partial x}{\partial \hat{x}} \right)^{2(q+1)}$ in the action. From this term, it can be postulated that the action can be

$$S_{GDBI} = - \int d^{p+1}x \frac{1}{g_b} \left(-\det g \right)^{\frac{q}{2(q+1)}} \left[-\det \left(g + (C + H) \tilde{g}^{-1} (C + H)^T \right) \right]^{\frac{1}{2(q+1)}} \quad (52)$$

because the term $\left(\det \frac{\partial x}{\partial \hat{x}} \right)^{2(q+1)}$ cancels with the Jacobian which arises from coordinate transformation, such that the Lagrangian is an integral density. The coupling constant

g_b is called closed brane coupling constant. We can also rewrite the open brane coupling constant G_b as

$$G_b = g_b \left(\frac{\det G}{\det g} \right)^{\frac{q}{2(q+1)}} \left(\frac{\det (G + \Phi \tilde{G}^{-1} \Phi^T)}{\det (g + C \tilde{g}^{-1} C^T)} \right)^{\frac{1}{2(q+1)}} = g_b \left(\frac{\det G}{\det g} \right)^{\frac{q}{2(q+1)}}. \quad (53)$$

We used

$$G + \Phi \tilde{G}^{-1} \Phi^T = g + C \tilde{g}^{-1} C^T \quad (54)$$

in the last equality. The action of the generalized DBI can be rewritten by using the open brane parameters.

$$\begin{aligned} & - \int d^{p+1}x \frac{1}{g_b} \left(-\det g \right)^{\frac{q}{2(q+1)}} \left[-\det \left(g + (C + H) \tilde{g}^{-1} (C + H)^T \right) \right]^{\frac{1}{2(q+1)}} \\ &= - \int d^{p+1}x \frac{1}{G_b} \left(-\det G \right)^{\frac{q}{2(q+1)}} \left[-\det \left(g + (C + H) \tilde{g}^{-1} (C + H)^T \right) \right]^{\frac{1}{2(q+1)}} \\ &= - \int d^{p+1}x \frac{1}{G_b} \left(-\det G \right)^{\frac{q}{2(q+1)}} \det^{\frac{1}{(q+1)}} \left(1 - H \Pi^T \right) \left[-\det \left(G + \Phi' \tilde{G}^{-1} \Phi'^T \right) \right]^{\frac{1}{2(q+1)}} \\ &= - \int d^{p+1}\hat{x} \frac{1}{\hat{G}_b} \left(-\det \hat{G} \right)^{\frac{q}{2(q+1)}} \det^{\frac{1}{(q+1)}} \left(\frac{\hat{\Pi}}{\Pi} \right) \left[-\det \left(\hat{G} + \hat{\Phi}' \hat{\tilde{G}}^{-1} \hat{\Phi}'^T \right) \right]^{\frac{1}{2(q+1)}}. \end{aligned} \quad (55)$$

This action is based on the equivalence between the non-commutative and commutative gauge theories. The closed-open relations can be generalized from the generalized metric. On the other hand, it can also be derived from the Nambu-Sigma model. If we consider a 2-form background, it goes back to the DBI theory. If we choose a 3-form background and set $p=5$, the action is

$$\begin{aligned} S_{5\text{-DBI}} &= - \int d^6x \frac{1}{g_b} \sqrt{-\det g} \det^{\frac{1}{6}} \left(1 + g^{-1} (C + H) \tilde{g}^{-1} (C + H)^T \right) \\ &\approx - \int d^6x \frac{1}{g_b} \sqrt{-\det g} \left(1 + \frac{1}{3} \text{Tr} k - \frac{1}{6} \text{Tr} k^2 + \frac{1}{18} (\text{Tr} k)^2 + \dots \right)^{\frac{1}{2}}, \end{aligned} \quad (56)$$

where $k^\mu{}_\nu = \frac{1}{2} (H + C)^{\mu\rho\sigma} (H + C)_{\nu\rho\sigma}$. This action is consistent with [47] up to the second order. The supersymmetric extension and other formulations of the membrane theory are in [48, 49].

3 Consistency of the Dimensional Reduction

In this section, we discuss the dimensional reduction of the action (52) without scalar fields. We first show the dimensional reduction from $(q+1)$ -($p+1$) to q - p . We only consider flat spacetime, constant antisymmetric background, and $(q+1)$ -form gauge field in $(q+1)$ -dimensional worldvolume directions (without a time direction) in q - p system. In other words, we have two types worldvolume directions. We use the non-dotted Greek letters to indicate the worldvolume directions without the antisymmetric background field and the dotted Greek letters to indicate the worldvolume directions with the antisymmetric background field. For a consistent notation, we define $(\dot{1}, \dot{2}, \dots, \dot{q}) \equiv (p-q, p-q+1, \dots, p-1)$. The generalized DBI theory (52) gives

$$\begin{aligned} S_{q+1,p+1} &= - \int d^{p+2}x \frac{1}{g_b} \det^{\frac{1}{2(q+2)}} \left(\delta_A^B + H_{Ai} \tilde{g}^{ij} H_{Cj} g^{CB} \right) \\ &= - \int d^{p+2}x \frac{1}{g_b} \exp \left[\frac{1}{2(q+2)} \text{Tr} \ln \left(\delta_A^B + H_{Ai} \tilde{g}^{ij} H_{Cj} g^{CB} \right) \right] \\ &= - \int d^{p+2}x \frac{1}{g_b} \exp \left[\frac{1}{2(q+2)} \text{Tr} \left(\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} (H_{Ai} \tilde{g}^{ij} H_{Cj} g^{CB})^n \right) \right]. \end{aligned} \quad (57)$$

We used

$$\det^x(I + M) = \exp \left(x \text{Tr} \ln(I + M) \right), \quad \ln(1 - x) = - \sum_{n=1}^{\infty} \frac{x^n}{n} \quad (58)$$

to get the second and third equalities respectively. Then we calculate $H_{Ai} \tilde{g}^{ij} H_{Cj} g^{CB}$

$$\begin{aligned} H_{Ai} \tilde{g}^{ij} H_{Cj} g^{CB} &= \frac{1}{((q+1)!)^2} H_{AC_1 \dots C_{q+1}} \sum_{\pi \in \sigma_{q+1}} \text{sgn}(\pi) \left(g^{C_{\pi(1)} D_1} g^{C_{\pi(2)} D_2} \dots g^{C_{\pi(q+1)} D_{q+1}} \right) H_{ED_1 \dots D_{q+1}} g^{EB} \\ &= \frac{1}{((q+1)!)^2} \sum_{\pi \in \sigma_{q+1}} \text{sgn}(\pi) H_A^{D_{\pi(1)} \dots D_{\pi(q+1)}} H^B_{D_1 \dots D_{q+1}} \\ &= \frac{1}{(q+1)!} H_A^{D_1 \dots D_{q+1}} H^B_{D_1 \dots D_{q+1}} \\ &\equiv \frac{1}{(q+1)!} (H^2)_A^B. \end{aligned}$$

The non-zero components in $(H^2)_A^B$ are

$$(H^2)_{p-q}^{p-q} = (H^2)_{p-q+1}^{p-q+1} = \dots = (H^2)_{p+1}^{p+1} = (q+1)! (H^2_{p-q, p-q+1, \dots, p+1}). \quad (59)$$

Substituting the result and taking trace in the action (57), we get

$$\begin{aligned}
S_{q+1,p+1} &= - \int d^{p+2}x \frac{1}{g_m} \exp \left(\frac{1}{2(q+2)} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} (q+2) (H_{p-q,p-q+1,\dots,p+1})^{2n} \right) \\
&= - \int d^{p+2}x \frac{1}{g_m} \sum_{m=0}^{\infty} \frac{1}{m!} \left(\frac{1}{2} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} (H_{p-q,p-q+1,\dots,p+1})^{2n} \right)^m. \tag{60}
\end{aligned}$$

Now we discuss the consistent truncation before we do the dimensional reduction. The equation of motion of the generalized DBI theory at the leading order is

$$\partial_A H^{Ai} = 0. \tag{61}$$

We first fix the gauge such that a equation of motion of the generalized DBI theory becomes the wave equation at the leading order. When we compactify one direction, it becomes periodic.. The solution is proportional to $\exp(i\frac{n}{R}y)$, where R is radius of the compact torus, n is the number of modes and y is the compacted coordinate. This periodic function gives a mass term in the equation of motion. When we shrink the radius to zero, the non-zero modes give the infinite mass and decouple from our theory consistently.

If we compactify one direction and shrink the radius to zero, the $(q+1)$ -form field strength becomes the q -form field strength. The expression (60) simply becomes

$$S_{q,p} = - \int d^{p+1}x \frac{1}{g_m} \sum_{m=0}^{\infty} \frac{1}{m!} \left(\frac{1}{2} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} (H_{p-q,p-q+1,\dots,p})^{2n} \right)^m. \tag{62}$$

In conclusion, we start from a system of $(q+1)$ -($p+1$), we can get an effective action for q - p system by the dimensional reduction.

We want to emphasize that this is *not* a trivial check because the $2(q+1)$ -th root in the action is so far predicted based on the equivalence between non-commutative and commutative gauge theories. This calculation in this simple example shows that the non-trivial power of this theory is also supported by the dimensional reduction.

4 Comments on Pull-Back

If we further require that the generalized DBI model can be reduced from $(q+1)$ -($p+1$) to q - p with scalar fields (by pull-back), the generalized DBI theory (52) needs to include an

one-form gauge potential for the $U(1)$ gauge symmetry. In the non-commutative gauge theory, we have these similar systems [50, 51, 52]. We discuss the possibility to extend the theory via the dimensional reduction. In this section, we show that inclusion of the one-form gauge field up to H^2 should be possible.

4.1 Scalar Field and Gauge Potential

When a worldvolume direction is compactified, the component of the compactified direction of a gauge potential A^I gives a scalar field X^I ,

$$A^I \rightarrow X^I, \quad F^{AI} \rightarrow \partial^A X^I. \quad (63)$$

The scalar field X^I correspond to the positions of a brane in the transverse directions.

We introduce a scalar field from the pull-back. In the static gauge and the case of flat spacetime, we have

$$g_{AB} = \eta_{AB} + \partial_A X^I \partial_B X^I. \quad (64)$$

The inverse of this metric is

$$g^{AB} = \eta^{AB} + \sum_{n=1}^{\infty} (-1)^n \left(\partial^A X^{I_1} \right) \left(\partial_{D_1} X^{I_1} \right) \left(\partial^{D_1} X^{I_2} \right) \cdots \left(\partial_{D_{n-1}} X^{I_{n-1}} \right) \left(\partial^{D_{n-1}} X^{I_n} \right) \left(\partial^B X^{I_n} \right), \quad (65)$$

which indeed satisfies a condition $g_{AB} g^{BC} = \delta_A^C$. We define

$$\omega^{AB} \equiv \sum_{n=1}^{\infty} (-1)^n \left(\partial^A X^{I_1} \right) \left(\partial_{D_1} X^{I_1} \right) \left(\partial^{D_1} X^{I_2} \right) \cdots \left(\partial_{D_{n-1}} X^{I_{n-1}} \right) \left(\partial^{D_{n-1}} X^{I_n} \right) \left(\partial^B X^{I_n} \right) \quad (66)$$

for convenience and it is symmetric under interchanging the indices, i.e., $\omega^{AB} = \omega^{BA}$.

4.2 $(q+1)-(p+1) \rightarrow q-p$

We show that the effective action of a $q-p$ brane system without the one-form gauge potential can be deduced from the $(q+1)-(p+1)$ system up to H^2 order.

We also assume that only $\dot{\alpha}$ components of H are turned on. The action is

$$\begin{aligned}
S_{q+1,p+1} &= - \int d^{p+2}x \frac{1}{g_b} \sqrt{-\det g} \det^{\frac{1}{2(q+2)}} \left(\delta_A^B + H_{Ai} \tilde{g}^{ij} H_{Cj} g^{CB} \right) \\
&= - \int d^{p+2}x \frac{1}{g_b} \sqrt{-\det g} \exp \left[\frac{1}{2(q+2)} \text{Tr} \left(\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} (H_{Ai} \tilde{g}^{ij} H_{Cj} g^{CB})^n \right) \right].
\end{aligned} \tag{67}$$

For $n = 1$, we can obtain

$$\begin{aligned}
&\text{Tr} \left(H_{Ai} \tilde{g}^{ij} H_{Cj} g^{CB} \right) \\
&= H_{p-q,p-q+1,\dots,p+1}^2 \sum_{k=0}^{q+1} \sum_{\dot{\alpha}_k, \dot{\beta}_k, \dot{\gamma}_k=p-q}^{p+1} \frac{q+2}{k!(q+2-k)!} \\
&\quad \times \epsilon_{\dot{\alpha}_1 \dot{\alpha}_2 \dots \dot{\alpha}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+2}} \epsilon_{\dot{\beta}_1 \dot{\beta}_2 \dots \dot{\beta}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+2}} \omega^{\dot{\alpha}_1 \dot{\beta}_1} \omega^{\dot{\alpha}_2 \dot{\beta}_2} \dots \omega^{\dot{\alpha}_k \dot{\beta}_k},
\end{aligned} \tag{68}$$

where $\epsilon_{\dot{\alpha}_1 \dot{\alpha}_2 \dots \dot{\alpha}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+2}}$ and $\epsilon_{\dot{\beta}_1 \dot{\beta}_2 \dots \dot{\beta}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+2}}$ are Levi-Civita symbols. The factorials $k!$ and $(q+2-k)!$ are used to cancel the factor of overcounting such that the coefficients of each term in the summation is simply unity. The expression (67) becomes

$$\begin{aligned}
S_{q+1,p+1} &= - \int d^{p+1}x \frac{1}{g_b} \sqrt{-\det g} \\
&\quad \exp \left(\frac{1}{2} H_{p-q,p-q+1,\dots,p+1}^2 \sum_{k=0}^{q+1} \sum_{\dot{\alpha}_k, \dot{\beta}_k, \dot{\gamma}_k=p-q}^{p+1} \frac{1}{k!(q+2-k)!} \right. \\
&\quad \left. \times \epsilon_{\dot{\alpha}_1 \dot{\alpha}_2 \dots \dot{\alpha}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+2}} \epsilon_{\dot{\beta}_1 \dot{\beta}_2 \dots \dot{\beta}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+2}} \omega^{\dot{\alpha}_1 \dot{\beta}_1} \omega^{\dot{\alpha}_2 \dot{\beta}_2} \dots \omega^{\dot{\alpha}_k \dot{\beta}_k} + \dots \right).
\end{aligned} \tag{69}$$

The factors $(q+2)$ in (67) and (68) cancel out each other. If we compactify one worldvolume direction with background, say $p+1$, and shrink the radius to zero, then all $\omega^{\dot{\alpha}(p+1)}$ vanish. This is equivalent to excluding $p+1$ in the summation, that is

$$\begin{aligned}
\sum_{\{\dot{\alpha}_k, \dot{\beta}_k, \dot{\gamma}_k=p-q\}}^{p+1} &\rightarrow \sum_{\{\dot{\alpha}_k, \dot{\beta}_k, \dot{\gamma}_k=p-q\}}^p \\
\sum_{k=0}^{q+1} &\rightarrow \sum_{k=0}^q
\end{aligned} \tag{70}$$

On the other hand, the Levi-Civita symbols should be modified to

$$\epsilon_{\dot{\alpha}_1 \dot{\alpha}_2 \dots \dot{\alpha}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+2}} \epsilon_{\dot{\beta}_1 \dot{\beta}_2 \dots \dot{\beta}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+2}} \rightarrow (q+2-k) \epsilon_{\dot{\alpha}_1 \dot{\alpha}_2 \dots \dot{\alpha}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+1}} \epsilon_{\dot{\beta}_1 \dot{\beta}_2 \dots \dot{\beta}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+1}}. \quad (71)$$

As a result, the action (69) becomes

$$\begin{aligned} S_{q,p} = & - \int d^{p+1}x \frac{1}{g_b} \sqrt{-\det g} \\ & \times \exp \left(\frac{1}{2} H_{p-q, p-q+1, \dots, p}^2 \sum_{k=0}^q \sum_{\dot{\alpha}_k, \dot{\beta}_k, \dot{\gamma}_k = p-q}^p \frac{1}{k!(q+1-k)!} \right. \\ & \left. \times \epsilon_{\dot{\alpha}_1 \dot{\alpha}_2 \dots \dot{\alpha}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+1}} \epsilon_{\dot{\beta}_1 \dot{\beta}_2 \dots \dot{\beta}_k \dot{\gamma}_{k+1} \dot{\gamma}_{k+2} \dots \dot{\gamma}_{q+1}} \omega^{\dot{\alpha}_1 \dot{\beta}_1} \omega^{\dot{\alpha}_2 \dot{\beta}_2} \dots \omega^{\dot{\alpha}_k \dot{\beta}_k} + \dots \right), \end{aligned} \quad (72)$$

which is exactly the action (69) with $q+1$ and $p+1$ replaced by q and p respectively. This calculation shows the possibility to include the one-form gauge field in the theory up to H^2 order.

5 Conclusion

The generalized DBI is aimed for describing a q -brane ending on a p -brane. The most non-trivial feature of this action is the $2(q+1)$ -th root, which is predicted by the existence of the equivalence between the commutative and non-commutative descriptions of the q - p system. In this paper, we showed that the non-trivial power of the generalized DBI action can be consistent with the dimensional reduction. The calculation provides more evidences to the relation between 2-5 and M2-M5 system. In addition, we also find the possibility to extend the theory by adding the one-form gauge field in the presence of scalar fields from the dimensional reduction. We leave the full understanding of the dimensional reduction for $(q+1)$ - $(p+1) \rightarrow q$ - p to the future. We can, of course, consider dimensional reduction along a direction orthogonal to the worldvolume directions. However, in our simple consideration, the background is not modified under this kind of the dimensional reduction. This should be trivial in this case. This direction should be a starting point to address the interesting issue of the duality structure of the higher-form fields. Although it is not a general study, we do not have many studies in the higher-form fields.

The supersymmetric extension of this theory should be able to give a direct link between the supergravity and generalized DBI theory. With the perturbative calculation up to the second order, we can obtain a similar form for the M5-brane [47], which already has a supersymmetric extension. Although it is hard to find the supersymmetric theory for the DBI-form theory, we should be able to perform perturbative calculation order by order in principle.

So far, the relation between the generalized DBI theory and generalized geometry is unclear. However, the key point is that the generalized DBI theory is constructed by the equivalence between the commutative and non-commutative gauge theories. This equivalence is further governed by the generalized metric, which is always an important element in the generalized geometry. We expect that a generalized geometrical structure for $q > 1$ can be found.

The most interesting extension should be the T-duality rule between the background fields. Of course, we still have the familiar Buscher's rule for $q=1$ with different values of p . Certainly, study of the T-duality rule of the generalized DBI theory is a challenging and interesting problem. The T-duality of the generalized DBI theory should be interesting on higher dimensional field theories (larger than eleven dimensions).

Finally, we remark on one related direction—double field theory of the DBI. By now, we do not get any insight to put the one-form gauge field in the double field theory. This is still an open problem. The starting point is to find the gauge transformation related to the Courant bracket. This should offer an unique structure to constrain the DBI theory in the double field theory. One more interesting prospect related to the open string of the double field theory is to understand the string sigma model with the manifest Buscher's rule. It is a well-known fact that the DBI model is equivalent to the calculation of the one-loop β function of the string sigma model. If we can include the strong constraints in the double field theory of the string sigma model, the one-loop β function would be an important consistent check. Moreover, one-loop β function of the Nambu-Sigma model is also an important problem. So far, we only used the generalized metric and equivalence between the commutative and non-commutative descriptions to understand the generalized DBI model. We expect that the one-loop β function of the Nambu-Sigma model should lead to the generalized DBI theory.

A The Generalized Closed-Open Relations

We determine g explicitly by

$$\begin{aligned}
g^{-1} &= \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \\
&\quad - \left[- \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \Phi \tilde{G}^{-1} \left(\tilde{G} + \Phi^T G^{-1} \Phi \right) + \Pi \left(\tilde{G} + \Phi^T G^{-1} \Phi \right) \right] \\
&\quad \times \left[\tilde{G}^{-1} \Phi^T \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} - \Pi^T \right] \\
&= \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} + \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \Phi \tilde{G}^{-1} \left(\tilde{G} + \Phi^T G^{-1} \Phi \right) \tilde{G}^{-1} \Phi^T \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \\
&\quad - \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \Phi \tilde{G}^{-1} \left(\tilde{G} + \Phi^T G^{-1} \Phi \right) \Pi^T - \Pi \left(\tilde{G} + \Phi^T G^{-1} \Phi \right) \tilde{G}^{-1} \Phi^T \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \\
&\quad + \Pi \left(\tilde{G} + \Phi^T G^{-1} \Phi \right) \Pi^T.
\end{aligned} \tag{73}$$

Before showing the explicit answer, we show the trick for simplifying the third and fourth terms. The third term is

$$\begin{aligned}
& - \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \Phi \tilde{G}^{-1} \left(\tilde{G} + \Phi^T G^{-1} \Phi \right) \Pi^T \\
&= - \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \left(\Phi + \Phi \tilde{G}^{-1} \Phi^T G^{-1} \Phi \right) \Pi^T \\
&= - \left[\left(G + \Phi \tilde{G}^{-1} \Phi^T \right) G^{-1} \Phi \left(G^{-1} \Phi \right)^{-1} \right]^{-1} \left(\Phi + \Phi \tilde{G}^{-1} \Phi^T G^{-1} \Phi \right) \Pi^T \\
&= - G^{-1} \Phi \Pi^T.
\end{aligned} \tag{74}$$

The fourth term is

$$\begin{aligned}
& - \Pi \left(\tilde{G} + \Phi^T G^{-1} \Phi \right) \tilde{G}^{-1} \Phi^T \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \\
&= - \Pi \left(\Phi^T + \Phi^T G^{-1} \Phi \tilde{G}^{-1} \Phi^T \right) \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \\
&= - \Pi \left(\Phi^T + \Phi^T G^{-1} \Phi \tilde{G}^{-1} \Phi^T \right) \left[\left(\Phi^T G^{-1} \right)^{-1} \Phi^T G^{-1} \left(G + \Phi \tilde{G}^{-1} \Phi^T \right) \right]^{-1} \\
&= - \Pi \Phi^T G^{-1}.
\end{aligned} \tag{75}$$

By using the same method, the first and second terms are

$$\begin{aligned}
& \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} + G^{-1} \Phi \tilde{G}^{-1} \Phi^T \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \\
&= \left(1 + G^{-1} \Phi \tilde{G}^{-1} \Phi^T \right) \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \\
&= G^{-1}.
\end{aligned} \tag{76}$$

We can see the explicit answer by combining all terms

$$g^{-1} = \left(1 - \Phi \Pi^T \right)^T G^{-1} \left(1 - \Phi \Pi^T \right) + \Pi \tilde{G} \Pi^T. \tag{77}$$

Then we can determine C

$$\begin{aligned}
C &= - \left[\left(1 - \Phi \Pi^T \right)^T G^{-1} \left(1 - \Phi \Pi^T \right) + \Pi \tilde{G} \Pi^T \right]^{-1} \\
&\quad \times \left[- \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \Phi \tilde{G}^{-1} + \Pi \right] \left(\tilde{G} + \Phi^T G^{-1} \Phi \right) \\
&= \left[\left(1 - \Phi \Pi^T \right)^T G^{-1} \left(1 - \Phi \Pi^T \right) + \Pi \tilde{G} \Pi^T \right]^{-1} \left[\left(1 - \Phi \Pi^T \right)^T G^{-1} \Phi - \Pi \tilde{G} \right].
\end{aligned} \tag{78}$$

The expression for \tilde{g}^{-1} can also be derived

$$\begin{aligned}
\tilde{g}^{-1} &= \left(\tilde{G} + \Phi^T G^{-1} \Phi \right)^{-1} \\
&\quad + \left[\tilde{G}^{-1} \Phi^T - \Pi^T \left(G + \Phi \tilde{G}^{-1} \Phi^T \right) \right] \left[\left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \Phi \tilde{G}^{-1} - \Pi \right] \\
&= \left(\tilde{G} + \Phi^T G^{-1} \Phi \right)^{-1} + \tilde{G}^{-1} \Phi^T \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \Phi \tilde{G}^{-1} \\
&\quad - \tilde{G}^{-1} \Phi^T \Pi - \Pi^T \Phi \tilde{G}^T + \Pi^T \left(G + \Phi \tilde{G}^{-1} \Phi^T \right) \Pi.
\end{aligned} \tag{79}$$

The first term can be rewritten by using the fact that

$$\left(a + b \right)^{-1} = a^{-1} - a^{-1} b \left(b + b a^{-1} b \right)^{-1} b a^{-1}. \tag{80}$$

The above formula can be derived from the Binomial Inverse Theorem. The first term is

$$\begin{aligned}
& \tilde{G}^{-1} - \tilde{G}^{-1} \left(\Phi^T G^{-1} \Phi \right) \left(\Phi^T G^{-1} \Phi + \Phi^T G^{-1} \Phi \tilde{G}^{-1} \Phi^T G^{-1} \Phi \right)^{-1} \Phi^T G^{-1} \Phi \tilde{G}^{-1} \\
&= \tilde{G}^{-1} - \tilde{G}^{-1} \Phi^T \left(\Phi^T + \Phi^T G^{-1} \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \Phi^T G^{-1} \Phi \tilde{G}^{-1} \\
&= \tilde{G}^{-1} - \tilde{G}^{-1} \Phi^T \left(1 + G^{-1} \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} G^{-1} \Phi \tilde{G}^{-1} \\
&= \tilde{G}^{-1} - \tilde{G}^{-1} \Phi^T \left(G + \Phi \tilde{G}^{-1} \Phi^T \right)^{-1} \Phi \tilde{G}^{-1}. \tag{81}
\end{aligned}$$

If we combine the first term and second terms, we obtain \tilde{G}^{-1} . We can combine all terms to derive

$$\tilde{g}^{-1} = (1 - \Phi^T \Pi)^T \tilde{G}^{-1} (1 - \Phi^T \Pi) + \Pi^T G \Pi. \tag{82}$$

B Calculations for the Construction of the Generalized DBI

The generalization of DBI can also be done by a similar decomposition of matrix as (41)

$$\begin{aligned}
& \begin{pmatrix} 1 & -H^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & -C^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \tilde{g} & 0 \\ 0 & g^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -C & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -H & 1 \end{pmatrix} \\
&= \begin{pmatrix} \tilde{g} + (C + H)^T g^{-1} (C + H) & -(C + H)^T g^{-1} \\ -g^{-1} (C + H) & g^{-1} \end{pmatrix} \\
&= \begin{pmatrix} 1 & -H^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \Pi & 1 \end{pmatrix} \begin{pmatrix} 1 & -\Phi^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \tilde{G} & 0 \\ 0 & G^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\Phi & 1 \end{pmatrix} \begin{pmatrix} 1 & \Pi^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -H & 1 \end{pmatrix} \\
&= \begin{pmatrix} 1 & -H^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \Pi & 1 \end{pmatrix} \begin{pmatrix} 1 & H^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & -(\Phi^T + H^T) \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \tilde{G} & 0 \\ 0 & G^{-1} \end{pmatrix} \\
&\quad \cdot \begin{pmatrix} 1 & 0 \\ -(\Phi^T + H^T) & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ H' & 1 \end{pmatrix} \begin{pmatrix} 1 & \Pi^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -H & 1 \end{pmatrix}. \tag{83}
\end{aligned}$$

We can add square matrix M and N in a similar way

$$\begin{pmatrix} 1 & 0 \\ \Pi' & 1 \end{pmatrix} \begin{pmatrix} N^T & 0 \\ 0 & M^T \end{pmatrix} \begin{pmatrix} 1 & -\Phi'^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \tilde{G} & 0 \\ 0 & G^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\Phi' & 1 \end{pmatrix} \begin{pmatrix} N & 0 \\ 0 & M \end{pmatrix} \begin{pmatrix} 1 & \Pi'^T \\ 0 & 1 \end{pmatrix}, \tag{84}$$

where $\Phi' = \Phi + H'$. From

$$\begin{aligned} & \begin{pmatrix} 1 & 0 \\ \Pi' & 1 \end{pmatrix} \begin{pmatrix} N^T & 0 \\ 0 & M^T \end{pmatrix} = \begin{pmatrix} N^T & 0 \\ \Pi' N^T & M^T \end{pmatrix} \\ &= \begin{pmatrix} 1 & -H^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \Pi & 1 \end{pmatrix} \begin{pmatrix} 1 & H'^T \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 - H^T \Pi & (1 - H^T \Pi) H'^T - H^T \\ \Pi & \Pi H'^T + 1 \end{pmatrix}, \end{aligned} \quad (85)$$

we can obtain

$$\begin{aligned} \Pi' &= \Pi \left(1 - H^T \Pi \right)^{-1}, \\ H' &= H \left(1 - \Pi^T H \right)^{-1}, \\ N &= 1 - \Pi^T H = \left(1 + \Pi^T H \right)^{-1}, \\ M &= 1 + H' \Pi^T = \left(1 - H \Pi^T \right)^{-1}. \end{aligned} \quad (86)$$

We find the useful formulae from

$$\begin{aligned} & \begin{pmatrix} 1 & 0 \\ \Pi' & 1 \end{pmatrix} \begin{pmatrix} N^T & 0 \\ 0 & M^T \end{pmatrix} \begin{pmatrix} 1 & -\Phi'^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \tilde{G} & 0 \\ 0 & G^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\Phi' & 1 \end{pmatrix} \begin{pmatrix} N & 0 \\ 0 & M \end{pmatrix} \begin{pmatrix} 1 & \Pi'^T \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} \tilde{g} + (C + H)^T g^{-1} (C + H) & -(C + H)^T g^{-1} \\ -g^{-1} (C + H) & g^{-1} \end{pmatrix}. \end{aligned} \quad (87)$$

Therefore, we get

$$\begin{aligned} \tilde{g} + (C + H)^T g^{-1} (C + H) &= N^T \left(\tilde{G} + \Phi'^T G^{-1} \Phi' \right) N, \\ -(C + H)^T g^{-1} &= N^T \left(\tilde{G} + \Phi' G^{-1} \Phi' \right) N \Pi'^T - N^T \Phi'^T G^{-1} M, \\ g^{-1} &= \Pi' N^T \tilde{G} N \Pi'^T + \left(-\Pi' N^T \Phi'^T + M^T \right) G^{-1} \left(-\Phi' N \Pi'^T + M \right). \end{aligned}$$

Thus, we have

$$\begin{aligned} \det \left(\tilde{g} + (C + H)^T g^{-1} (C + H) \right) &= \det^2(N) \det \left(\tilde{G} + \Phi'^T G^{-1} \Phi' \right) \\ &= \det^2(1 - \Pi^T H) \left(\tilde{G} + \Phi'^T G^{-1} \Phi' \right). \end{aligned} \quad (88)$$

From the bottom right block of

$$\begin{aligned}
& \begin{pmatrix} 1 & -\Pi'^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} N^{-1} & 0 \\ 0 & M^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \Phi' & 1 \end{pmatrix} \begin{pmatrix} \tilde{G}^{-1} & 0 \\ 0 & G \end{pmatrix} \begin{pmatrix} 1 & \Phi'^T \\ 0 & 1 \end{pmatrix} \begin{pmatrix} (N^T)^{-1} & 0 \\ 0 & (M^T)^{-1} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\Pi' & 1 \end{pmatrix} \\
&= \begin{pmatrix} \tilde{g} + (C + H)^T g^{-1} (C + H) & -(C + H)^T g^{-1} \\ -g^{-1} (C + H) & g^{-1} \end{pmatrix}^{-1}, \tag{89}
\end{aligned}$$

we obtain

$$\begin{aligned}
\det \left(g + (C + H) \tilde{g}^{-1} (C + H)^T \right) &= \det \left[M^{-1} \left(G + \Phi' \tilde{G}^{-1} \Phi'^T \right) \left(M^{-1} \right)^T \right] \\
&= \det^2 \left(1 - H \Pi^T \right) \det \left(G + \Phi' \tilde{G}^{-1} \Phi'^T \right). \tag{90}
\end{aligned}$$

In addition, we also have

$$\det \left(1 - \Pi^T H \right) = \det \left(1 - H \Pi^T \right) = \det \left(\frac{\hat{\Pi}}{\Pi} \right) \det^{q+1} \left(\frac{\partial x}{\partial \hat{x}} \right). \tag{91}$$
